

API Test Explanation Note.

Testing of the Boeing website (Merchandise part) API showed that only two types of POST and GET requests are formed on it. Unfortunately, when testing the site's API, I did not have any technical documentation, specifications, and business requirements, so I had to use Google Chrome Developer Tools to determine the types of requests, when performing operations that showed the real types of requests. In my opinion here when ordering goods, removing goods from the cart or adding goods to the cart, a wider range of queries could be used, such as POST, GET, PATCH, PUT and DELETE. Instead, only the two above were used. In addition, it is impossible to delete an already submitted user on the site, which, in my opinion, is wrong. Of course, it is possible that the developer received just such a task according to the specification and he was given the task of using only these two types of requests, we do not know this. However, these two types of requests do a good job of selecting, adding, and removing items from the cart.
